Acknowledgement

Our group would like to thank our lecturer for guidance on scoping and planning this project, and our classmates for testing early versions and giving feedback on the booking flow.

Summary

This report presents the main functions of RailSpeed, an online train ticket booking system. The pages were designed in Google Stitch and the system was built with Django (Python), Tailwind CSS and JavaScript. RailSpeed lets passengers search trips, choose a carriage and seat, pay by PromptPay QR and receive an e-ticket, while admins manage trains, schedules and bookings, all stored in the database.

Introduction

The purpose of this report is to describe RailSpeed, an online train ticket booking system for long-distance trains in Thailand. Today, many passengers still queue at station counters or book without seeing where they will sit or sleep. Our group built RailSpeed so passengers can see the whole train as carriages, choose their exact seat or berth, and pay by phone. The report also suggests future work to improve the system.

System Description

RailSpeed allows passengers to search train trips, choose a seat or sleeper berth on a seat map, enter passenger details and pay by PromptPay QR. After paying, the passenger uploads the payment slip and receives an e-ticket with a QR code once the booking is confirmed. Passengers can also view or cancel their bookings, edit their profile, contact the admin and ask an AI assistant about booking.

The admin is able to check payment slips, confirm or cancel bookings, edit passenger details, and manage stations, trains, carriages, schedules, prices, users and messages. All records are saved in the database.

Goals and Objectives of the people using the System

Firstly, passengers can book a train ticket online at any time without queuing at the station. Secondly, passengers can choose exactly where they sit or sleep and see which seats are already taken. Finally, admins can check payments and manage trains and schedules in one place, so mistakes are fixed quickly.

Main Function of the Application

1. All individuals can search train trips by route and date and see available seats and berths.
2. Registered users can choose a carriage and seat (up to 4 seats), and the seat is held for 15 minutes while they pay.
3. Users pay by PromptPay QR, upload the slip, and receive an e-ticket with a QR code.
4. Users can view, print or cancel their bookings in "My bookings".

5. An AI assistant answers questions about booking, trips and the user's own booking status.
6. Only admin can confirm payments and edit or cancel any booking.
7. Only admin can manage stations, trains, carriages, schedules, prices and user accounts.
8. Passwords are encrypted, and users can switch between light and dark mode.

Conclusion

By making this project, our group learned the full process of building a web application: designing the user interface, designing the database and writing the program code.

RailSpeed can be improved by adding an English version for tourists, automatic payment slip checking, email or LINE notifications when a booking is confirmed, and fares based on distance. In the near future, we believe the system can grow into a more complete and useful application.
